Abstract

The Barcode of Life Data Systems (BOLD) is designed to support the generation and application of DNA barcode data, but it also provides a unique source of data with potential for many research uses. This paper explores the streamlining of BOLD specimen data to record species distributions – and its fast publication using the Biodiversity Data Journal (BDJ), and its authoring platform, the Pensoft Writing Tool (PWT). We selected a sample of 630 specimens and 10 species of a highly diverse group of parasitoid wasps (Hymenoptera: Braconidae, Microgastrinae) from the Nearctic region and used the information in BOLD to uncover a significant number of new records (of locality, provinces, territories and states). By converting specimen information (such as locality, collection date, collector, voucher depository) from the BOLD platform to the Excel template provided by the PWT, it is possible to quickly upload and generate long lists of "Material Examined"

for papers discussing taxonomy, ecology and/or new distribution records of species. For the vast majority of publications including DNA barcodes, the generation and publication of ancillary data associated with the barcoded material is seldom highlighted and often disregarded, and the analysis of those data sets to uncover new distribution patterns of species has rarely been explored, even though many BOLD records represent new and/or significant discoveries. The introduction of journals specializing in – and streamlining – the release of these datasets, such as the BDJ, should facilitate thorough analysis of these records, as shown in this paper.

Species distribution records, streamlining data, Barcode of Life Data Systems, Pensoft Writing Tool, Microgastrinae, Nearctic

Introduction

The Barcode of Life Data Systems (BOLD) is designed to support the generation and application of DNA barcode data. The platform consists of four main modules: a data portal, a database of barcode clusters, an educational portal, and a data collection workbench. Currently almost 4 million sequences (over 3.4 million of them DNA barcodes) are stored in BOLD, including coverage for more than 143K animal species, 53K plant species, and 16K fungi and other species (<http://www.boldsystems.org/>, accessed on October 09, 2014). This immense platform provides a unique source of data with potential for many research uses. For example, the use of sequences in BOLD has been greatly expanded in the past few years, and dozens of publications using BOLD exist.

A less known and explored avenue is the use of specimen data (also stored in BOLD), which has a great potential to reveal new biodiversity information as well. This paper explores the streamlining of BOLD specimen data to record species distributions. For that we use the Biodiversity Data Journal (BDJ), and its authoring platform, the Pensoft Writing Tool (PWT), which is a community peer-reviewed, open-access, comprehensive online platform, designed to accelerate publishing, dissemination and sharing of biodiversity-related data of any kind (<http://biodiversitydatajournal.com/about#FocusandScope>).

A highly diverse group of insects (parasitoid wasps of the family Braconidae, subfamily Microgastrinae) was used as a case study. Microgastrine wasps are among the best represented groups of Hymenoptera in BOLD, and over 20K sequences have been already released and are publicly available (e.g., Smith et al. 2012). Microgastrinae is also one of the largest and most important groups of caterpillar parasitoids, with great importance in biological control programs worldwide (e.g., Whitfield 1997).

Materials and methods

All specimens used for this study are deposited in the collections of the Biodiversity Institute of Ontario, University of Guelph (BIO), or the Canadian National Collection of Insects, Ottawa (CNC). They represent dozens of collecting events and different research projects carried out by those institutions. Most of the specimens rendered partial or full DNA barcodes (information can be retrieved using the following public DOI: <http://dx.doi.org/10.5883/DS-NEAMICRO>), and many have associated sequences, images and/or data from their labels in collections (Suppl. materials 1, 2, 3, 4).

We selected a sample of 630 specimens of parasitoid wasps, representing ten species and five genera of Microgastrinae (Hymenoptera: Braconidae) from the Nearctic region (Canada and the United States). The identity of the species was confirmed by JFT against authenticated material deposited in the CNC.

We downloaded the “Data Spreadsheet” associated with those records, including the worksheets “Collection Data” and “Specimens Details” (for a detailed explanation consult the “BOLD Print Handbook for BOLD v3”, freely available online at http://www.boldsystems.org/libhtml_v3/static/BOLD_Handbook_Oct2013.pdf).

The Excel file downloaded from BOLD (Suppl. material 1) was then adapted to the template provided by BDJ (a DarwinCore Compliant Excel file). Fields that were of interest for this study (e.g., locality data, collecting date, collectors, institution storing the specimens) were pasted to the corresponding columns in the BDJ template (Suppl. material 2), and from there directly imported into the Pensoft Writing Tool (the tool used to produce manuscripts for consequent submission to the BDJ). The information was uploaded as part of “Materials” for every individual species included in this study.

We compared the known distributions of the species (using mostly Fernandez-Triana 2010, Fernandez-Triana et al. 2014, Whitfield 2006, Yu et al. 2012, Fernández-Triana and Huber 2010) against the information stored in BOLD. In doing so, a significant number of new records (of locality, provinces, territories and states) were uncovered, which are detailed and discussed for every individual species under the section “Notes”. The distribution records of the specimens involved in this study (Suppl. material 5) were mapped using SimpleMappr (<http://www.simplemappr.net>).

The ten species analyzed here represented 13 Barcode Index Numbers (BINS), sensu Ratnasingham and Hebert (2013). In three cases, single names were found to contain multiple clusters of COI variation (Suppl. materials 4, 5). Since such variation has often been ascribed to cryptic or hidden species we examine each case under the section “Notes” for those particular species.

A few specimens discussed in this paper did not render any DNA and thus do not have any associated sequence in BOLD. However, their ancillary data (e.g., collecting date, locality, etc.) was still available and thus is presented below.

When discussing the distribution of species, states of the United States and provinces/territories of Canada are abbreviated with acronyms consisting of two capital letters, following Canada Post standards (<http://www.canadapost.ca/tools/pg/manual/PGeaddress-e.asp>).

Species List

Apanteles carpatus (Say, 1836)

Notes: A cosmopolitan species (Yu et al. 2012), it was recorded from three provinces in Canada (BC, NB, ON) by Fernandez-Triana (2010), but no locality records were provided at the time. Here we present new details about the distribution of this species in Canada, based on examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

Notes: This species is widely distributed in central and eastern North America. It was recorded from two provinces in Canada (NS, ON) by Fernandez-Triana (2010), but no locality records were provided at the time. Here we present additional information about the distribution of this species in Canada, including five new provincial records (AB, NL, PE, QC, SK), based on examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

The specimens of *A. conanchetorum* that rendered DNA barcodes comprise two BINS: [BOLD:AAC5506](#) (eastern North America) and [BOLD:AAC5507](#) (principally Western Canada, but some records from ON, PE) (Suppl. material 4); whether they represent two different species or not will be studied in an upcoming paper.

Apanteles ensiger (Say, 1836)

Notes: This species is widely distributed in central and eastern North America. It was recorded from four provinces in Canada (MB, NS, ON, QC) by Fernandez-Triana (2010), but no locality records were provided at that time. Recently four more Canadian provinces and territories (AB, NB, NT, SK) and one state (AK) from the United States were added (Fernandez-Triana et al. 2014). Here we present additional information about the distribution of this species in the Nearctic, including two new provincial records for Canada (NL, PE) and one state (FL) from the United States, based on

examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

The specimens of *A. ensiger* that rendered DNA barcodes comprise two BINS, [BOLD:ACE6783](#) (ON, MB) and [BOLD:AAA3764](#) (AB, ON, SK and some localities of southern US) (Suppl. material 4); whether they represent two different species or not will be studied in an upcoming paper.

Apanteles sodalis (Haliday, 1834)

Notes: Previously, this species was known to be widely distributed in the Palaearctic, with one record from tropical Africa (Yu et al. 2012). It was recently recorded from three provinces in Canada (BC, MB, SK) by Fernandez-Triana et al. (2014). A new provincial record (NL) is added here, altogether with detailed information about the distribution of this species in Canada, based on examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

Notes: This species is relatively widely distributed in northeast North America, extending up to central Canada (Yu et al. 2012). It was recorded from five provinces in Canada (MB, NB, NS, ON, QC) by Fernandez-Triana (2010), but no locality records were provided at the time. Here we present additional information about the distribution of the species in Canada, including one new provincial record (PE), based on examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

***Pholetesor bedelliae* (Viereck, 1911)**

Notes: This species is widely distributed within the Nearctic (e.g., Whitfield 2006, Fernandez-Triana 2010, Yu et al. 2012, Fernandez-Triana et al. 2014), and is also reported from Finland (Hellén 1977), Peru (de Huiza 1995), and was introduced to Hawai (Yu et al. 2012). Here we present additional information about the distribution of this species in Canada, including one new provincial record (AB), based on examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

Pholetesor viminetus (Wesmael, 1837)

Notes: This species is widely distributed in the Holarctic (e.g., Whitfield 2006, Fernandez-Triana 2010, Yu et al. 2012, Fernandez-Triana et al. 2014). Here we present new and detailed information about the distribution of the species in Canada, including one new provincial record (ON), based on examined specimens from the BIO and CNC collections. Data for those specimens was extracted from BOLD.

Discussion

In addition to being a diverse platform for the generation, analysis and permanent storage of DNA barcodes, the Barcode of Life Data Systems (BOLD) houses an immense amount of collateral data that are only starting to be explored and exploited. Validated species

occurrences records are one such data element, critical for various fields and applications from environmental niche modeling in ecology to risk assessments in conservation biology. This paper demonstrates the potential of using BOLD occurrence data for these purposes – to define and refine the distributions of species – and presents a model for their rapid dissemination in the primary literature.

The key to this model is the seamless and dynamic transition of data between source and journal. By converting specimen information (such as locality, collection date, collector, voucher depository) from the BOLD platform to the Excel template provided by the Pensoft Writing Tool ([PWT](#)), the authoring platform of the Biodiversity Data Journal (BDJ), it is possible to quickly upload and generate long lists of "Material Examined" for papers discussing taxonomy, ecology and/or new distribution records of species. Additional functions in BOLD allow verification of this material, for instance the ability to generate high-res image libraries (e.g., Suppl. material 3) or Kimura 2-Parameter (K2P) phylogenograms using the corresponding sequences (e.g., Suppl. material 4). For the vast majority of publications including DNA barcodes, the generation and publication of ancillary data associated with the barcoded material is seldom highlighted and often disregarded. The analysis of those data sets to uncover new distribution patterns of species has rarely been explored, even though many BOLD records represent new and/or significant discoveries (but see Smith et al. (2012) for a discussion of this topic). The introduction of journals specializing in – and streamlining – the release of these datasets, such as the BDJ, should facilitate thorough analysis of these records, even large datasets. This paper used a moderately large data set (630 specimens comprising 10 species) and revealed several new distribution records, as well as the workflow that permitted their release (i.e., from a database to a publication).

The logical next step would be to create a simple interface and module at the source database (BOLD) that will submit data selected by the author, "at the click of a button", into the PWT, using the Application Programming Interface ([API](#)) of the latter. Within the PWT environment, the submitting author can complete the manuscript by adding additional text, figures, images, citations, references and so on. The author can also invite co-authors and/or "contributors" (e.g., linguistic editors, mentors, colleagues who are not formal co-authors) to collaboratively work on the manuscript. After completion, the manuscript is submitted to BDJ, again "at the click of a button", where it undergoes a community peer-review process and subsequent publication upon acceptance (e.g., Smith et al. 2013). The published article will contain dynamic links to external sources (Penev et al. 2010), including to BOLD, and will also be available in highly structured XML format which ensures machine readability of the text and data. For example, the occurrence records will automatically be exported to GBIF and appear there with their original source (e.g., BOLD) and publication source (reference for citation), bringing additional visibility and usage tracking statistics to both the source database and the authors. Visibility and usability are essential here, particularly for collateral data such as species occurrence records residing on BOLD, as the consumers and eventual uses of this biodiversity data are nearly as diverse as the organisms they represent.

Acknowledgements

The work of Pensoft on this project was partly supported by the EC-FP7 [EU BON](#) project (grant agreement №308454). Barcode analysis was facilitated by funding from the government of Canada through Genome Canada and the Ontario Genomics Institute in support of the [International Barcode of Life](#) project. The development of the [Barcode of Life Data Systems](#) (BOLD) was enabled by funding from the Ontario Ministry of Research and Innovation. JFT is grateful for the technical support of Teodor Georgiev and Pavel Stoev (Pensoft).
